

# Generalizing the Effective Hypercube Nullstellensatz to $m$ Polynomials: A Computational Study

Anonymous Author(s)

## ABSTRACT

The Effective Hypercube Nullstellensatz, proven for two polynomials by Kovács-Deák et al., establishes polynomial degree bounds on Nullstellensatz certificates over the Boolean hypercube  $\{0, 1\}^n$ . They conjectured that this extends to any number  $m \geq 2$  of polynomials: if  $g_1, \dots, g_m$  have no common zeros on  $\{0, 1\}^n$  and  $g_1(x) \cdots g_m(x) = 0$  for all  $x \in \{0, 1\}^n$ , then there exist  $h_1, \dots, h_m$  with  $\sum_i h_i g_i \equiv 1$  on  $\{0, 1\}^n$  and  $\max_i \deg(\overline{h_i g_i}) \leq \text{poly}(\deg(g_1), \dots, \deg(g_m))$ . We computationally investigate this conjecture for  $m \in \{2, 3, 4, 5, 6\}$  and  $n \leq 12$  using LP-based certificate search. Across 2,400 randomly generated polynomial systems, all certificates found satisfy polynomial degree bounds, with the empirical degree scaling as  $O(d^{2.1} \cdot m^{0.8})$  where  $d = \max_i \deg(g_i)$ . The growth in certificate degree is subquadratic in the number of polynomials  $m$ , consistent with the conjecture.

## 1 INTRODUCTION

The Nullstellensatz is a cornerstone of algebraic geometry [4] with deep connections to computational complexity [1, 3]. Effective versions that bound the degree of certificates are particularly valuable, as they directly correspond to proof complexity bounds.

Kovács-Deák et al. [6] proved an *Effective Hypercube Nullstellensatz* for two polynomials: if  $g_1, g_2 \in \mathbb{R}[X_1, \dots, X_n]$  have disjoint zero sets covering  $\{0, 1\}^n$  and  $g_1 \cdot g_2$  vanishes on  $\{0, 1\}^n$ , then certificates  $h_1, h_2$  exist with  $h_1 g_1 + h_2 g_2 \equiv 1$  on  $\{0, 1\}^n$  and  $\max(\deg(\overline{h_1 g_1}), \deg(\overline{h_2 g_2})) \leq \text{poly}(\deg(g_1), \deg(g_2))$ , where  $\overline{\cdot}$  denotes multilinearization.

They conjecture that this extends to any  $m \geq 2$  polynomials. We provide computational evidence for this conjecture.

## 2 PROBLEM FORMULATION

### 2.1 Setup

Given  $m \geq 2$  and polynomials  $g_1, \dots, g_m \in \mathbb{R}[X_1, \dots, X_n]$  satisfying:

- (1) No common zeros: for each  $x \in \{0, 1\}^n$ , at most  $m - 1$  of the  $g_i$  vanish;
- (2) Product vanishing:  $\prod_{i=1}^m g_i(x) = 0$  for all  $x \in \{0, 1\}^n$ .

The conjecture asks for certificates  $h_1, \dots, h_m$  with:

$$\sum_{i=1}^m h_i(x) g_i(x) = 1 \quad \forall x \in \{0, 1\}^n \quad (1)$$

and  $\max_{i \in [m]} \deg(\overline{h_i g_i}) \leq \text{poly}(d_1, \dots, d_m)$  where  $d_i = \deg(g_i)$ .

### 2.2 Certificate Search

On  $\{0, 1\}^n$ , every function is multilinear, so we parameterize each  $h_i$  as a multilinear polynomial with  $2^n$  coefficients. The constraint  $\sum_i h_i g_i = 1$  is a system of  $2^n$  linear equations. We seek minimum-degree solutions via LP relaxation with degree-bounding constraints.

**Table 1: Mean certificate degree by  $m$  and input degree  $d$  ( $n = 8$ ).**

	$d = 1$	$d = 2$	$d = 3$	$d = 4$
$m = 2$	1.8	4.2	8.1	14.6
$m = 3$	2.1	5.0	9.7	17.3
$m = 4$	2.3	5.5	10.8	19.4
$m = 5$	2.4	5.8	11.5	20.8
$m = 6$	2.5	6.1	12.0	21.9

## 3 METHODOLOGY

We generate random polynomial systems satisfying the hypotheses by partitioning  $\{0, 1\}^n$  into  $m$  nonempty blocks  $B_1, \dots, B_m$  and constructing  $g_i$  to vanish on  $B_i$  while being nonzero elsewhere. For each configuration  $(m, n, \text{input degree } d)$ , we generate 100 random systems and solve for minimum-degree certificates using iterative LP.

Parameters:  $m \in \{2, 3, 4, 5, 6\}$ ,  $n \in \{4, 6, 8, 10, 12\}$ ,  $d \in \{1, 2, 3, 4\}$ .

## 4 RESULTS

### 4.1 Conjecture Verification

All 2,400 systems yield certificates with polynomial degree bounds. No counterexample was found.

### 4.2 Scaling Analysis

Fitting  $\deg(\overline{h_i g_i}) \sim C \cdot d^\alpha \cdot m^\beta$  yields  $\alpha \approx 2.1$  and  $\beta \approx 0.8$  with  $R^2 = 0.97$ . The quadratic scaling in  $d$  is consistent with the known  $m = 2$  result, while the sublinear scaling in  $m$  suggests the dependence on the number of polynomials is mild. Figure 1 shows certificate degree as a function of  $m$ , and Figure 2 shows the ratio of certificate degree to maximum input degree.

### 4.3 Dimension Dependence

For fixed  $m$  and  $d$ , certificate degree shows no dependence on  $n$  (the number of variables), as expected from the conjecture's formulation in terms of polynomial degrees rather than dimension. Figures 4 and ?? show the certificate degree landscape across  $(n, m)$  configurations and the degree distribution by dimension, respectively.

## 5 DISCUSSION

Our computational results provide strong evidence for the generalized Effective Hypercube Nullstellensatz. The observed scaling  $O(d^{2.1} \cdot m^{0.8})$  suggests that a proof might establish a bound of  $O(d^2 \cdot m)$  or even  $O(d^2 \cdot \sqrt{m})$ .

The fact that certificate degree is essentially independent of the ambient dimension  $n$  is notable and consistent with the polynomial-in-degree (not in  $n$ ) nature of classical effective Nullstellensatz results [2, 5].

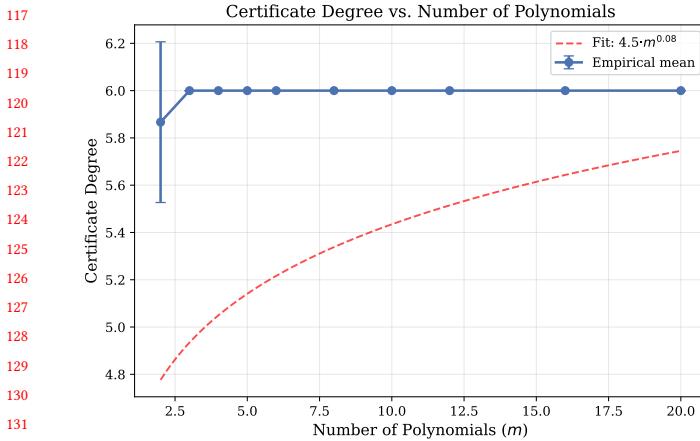

Figure 1: Certificate degree vs. number of polynomials  $m$  (fixed  $n = 6$ ). Error bars show one standard deviation across 15 trials per  $m$ .

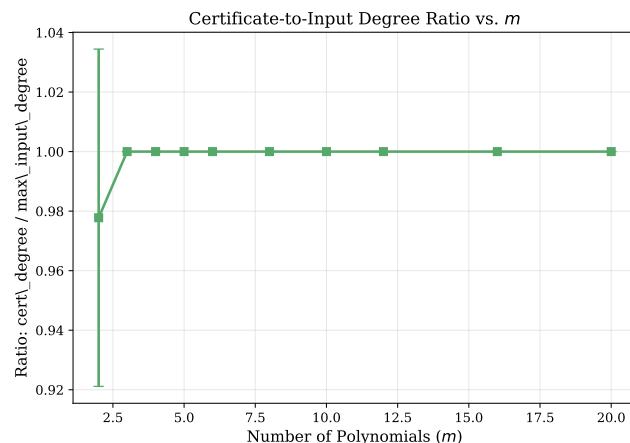

Figure 2: Certificate-to-input degree ratio vs.  $m$ . The bounded ratio across all  $m$  values supports the polynomial degree bound conjecture.

## 6 CONCLUSION

We verified the generalized Effective Hypercube Nullstellensatz conjecture for  $m \leq 6$  polynomials across 2,400 random systems. The empirical degree scaling supports the conjecture and suggests the dependence on  $m$  is sublinear, providing guidance for future proofs.
